

# Unintended Consequences of Coronavirus Disease-2019: Remember General Pediatrics

Valentino Cherubini, MD<sup>1</sup>, Anisha Gohil, DO<sup>2</sup>, Ananta Addala, DO, MPH<sup>3</sup>, Angela Zanfardino, MD<sup>4</sup>, Dario Iafusco, MD<sup>4</sup>, Tamara Hannon, MD<sup>2</sup>, and David M. Maahs, MD, PhD<sup>3</sup>

Coronavirus disease-2019 has disrupted pediatric healthcare. Observation of public health principles are vital. However, coronavirus disease-2019 has had unintended consequences on standard pediatric care. We describe cases of delayed diagnosis of diabetes leading to severe diabetic ketoacidosis; our aim is to highlight the need to apply basic pediatric principles for optimal care. (*J Pediatr* 2020;223:197-8).

In this time of coronavirus disease-2019 (COVID-19), shelter-in-place mandates that have clearly limited the spread of the pandemic also may have unintended consequences of delayed presentation of pediatric disease, precluding timely diagnosis and treatment. This can result in increased morbidity and mortality.

We describe cases of delayed diagnosis of new-onset type 1 diabetes (T1D) leading to presentation in severe diabetic ketoacidosis (DKA) with the aim of highlighting the need to remember basic pediatric principles to provide optimal care. Fear of contracting COVID-19 in a hospital setting, the inability to contact a medical provider for timely evaluation, and lack of consideration of DKA in the differential diagnosis at presentation are described. In addition to new-onset T1D, other pediatric diagnoses may be delayed owing to the focus on COVID-19 and DKA serves as a paradigm for these concerns.

## California Case

An 8-year-old boy with no significant past medical history presented to the emergency room in severe DKA after 5 days of emesis and abdominal pain as well as multiple contacts with medical providers. Three days before admission, the family was concerned about the persistent symptoms and contacted the urgent line provided by their insurance carrier, but did not receive a response. Another provider advised them to continue symptomatic management of abdominal pain and support with oral fluids as tolerated. One day before admission, the family noticed his difficulty breathing and called 911. First responders arrived and advised the family to be cautious about seeking additional medical visits or going to an emergency room to avoid unnecessary risk of exposure given the COVID-19 global pandemic. No laboratory tests were performed.

On the morning of presentation, his labored respirations continued and he subsequently developed altered mental

status, which prompted the family to take him to the local emergency room. On arrival, he was normotensive but tachycardic (blood pressure, 115/72 mm Hg; heart rate of 102), tachypneic (respiratory rate of 28), and hypothermic (34.9°C) with severe acidosis (pH 6.895, bicarbonate <5, and anion gap 23), hyperglycemia (873 mg/dL), and dehydration (blood urea nitrogen 39 and creatinine 1.1). He was hospitalized for 4 days in intensive care.

## Italy Cases

The COVID-19 pandemic has prompted strict quarantine measures in Italy, including suggesting hospital referrals only for urgent needs. Although important, this situation has created fear in the people of Italy who have reduced, or completely cancelled, outpatient visits to the hospital or health office for chronic diseases. In Italy, people usually turn to the hospital's emergency service not only for diseases that require emergency care, but also for nonserious clinical conditions, especially at night. As a consequence of quarantine measures, access to the emergency hospital has been dramatically reduced, resulting in reduced admissions also to children's hospitals.

Another impact is the quantity of phone calls received by hospital doctors focused on suspected COVID-19 and its screening. Other life-threatening diseases, namely T1D, without clinical symptoms of COVID-19 infection, are not being considered. The decreased number of children reported recently in Italy with newly diagnosed T1D during COVID-19 may indicate that appropriate conversations are not taking

place for prompt diagnosis leading to more severe presentation in DKA.

Three cases of severe DKA with a pH of less than 6.8 presented in the same week after the national lockdown because patients had been advised to stay at home because of the quarantine. The most striking case involved a 15-year-old girl who showed clear signs of polyuria and polydipsia for a week. Her parents, both physicians, suspected that she had T1D and discussed the need for a urinalysis to test for glucose and ketones; after 2 days, to overcome her parent's hesitation, she tasted her urine, confirming the presence of glucose by the sweet taste. Owing to her actions, she arrived at the hospital in relatively good condition (pH 7.2, blood glucose 385 mg/dL). However, it raises the question: does the fear of COVID-19 bring us back to the time of Apollinaire Boucharat, who taught patients to taste their own urine?<sup>1</sup>

### Indiana Case

A 17-year-old girl with a history of several weeks of polyuria and polydipsia, and a subjective 20-pound weight loss, sought care at an outpatient respiratory clinic owing to shortness of breath, sore throat, and cough. Her mother mentioned her daughter's polyuria and polydipsia, but the main concern was whether she had COVID-19. She was tested for coronavirus, streptococcus, and the flu which were all negative. She was prescribed an antibiotic to treat a skin rash and was sent home. Three days later, owing to worsening shortness of breath she presented to an outside emergency department and was found to be in DKA requiring intensive care unit admission (bicarbonate 7, blood glucose 434 mg/dL).

Most pediatricians appreciate that DKA may present similar to a viral illness and to inquire about symptoms of

polyuria, polydipsia, weight loss, fatigue, and (later) Kussmaul respirations and a "fruity," breath indicating advanced ketosis. Such a history combined with widely available tests such as a urine dipstick for glucose and ketones and a fingerstick for blood glucose avoid potentially deadly delays in T1D diagnosis. It is standard practice for pediatric endocrinologists to manage patients with known T1D at home by phone or telehealth, when indicated, to avoid need for urgent care in an emergency department. However, concerns of COVID-19 should not prevent appropriate referral for needed care for a known patient with T1D or if new-onset T1D is suspected.

In addition to DKA, we would expect other pediatric conditions to continue to happen and these cases should serve as a reminder to watch the basics of pediatrics in the time of COVID. Appropriate measures to prevent the spread of COVID-19 are vitally important. However, we must not let the fear of COVID-19, from health professionals and the general population, delay the diagnosis and prompt treatment T1D and other pediatric conditions. ■
