

# Coexisting overexpression of STOML1 and STOML2 proteins may be associated with pathology of oral squamous cell carcinoma

Daiwei Wang, PhD,<sup>a,b</sup> Hong Qi, MD,<sup>c</sup> Ang Li, PhD,<sup>c</sup> Fang Deng, MS,<sup>a</sup> Ying Xu, PhD,<sup>a</sup> Zhangli Hu, PhD,<sup>a</sup> Qiong Liu, PhD,<sup>a,b</sup> and Yun Wang, MD<sup>a</sup>

**Objective.** The present study aimed to investigate the expression and co-localization of stomatin-like protein-1 (STOML1) and stomatin-like protein-2 (STOML2) in oral squamous cell carcinoma (OSCC) tissues in situ and evaluate their pathologic roles in OSCC.

**Study Design.** STOML1 and STOML2 in human OSCC tissues (n = 109) and normal oral/paracancerous tissues (n = 19) were detected by using multiple immunohistochemistry (IHC) staining. Positive staining scores and clinicopathologic features during the OSCC process were analyzed.

**Results.** STOML1 and STOML2 were significantly overexpressed in OSCC tissues compared with normal oral tissue/paracancerous tissues ( $P < .0001$  and  $P < .0001$ , respectively). Furthermore, both STOML1 and STOML2 were positively associated with pathologic tumor (T) stages. Positive signals of both STOML1 and STOML2 were mainly localized to the cell membrane and the cytoplasm, whereas those of STOML1 were also expressed in the cell nucleus.

**Conclusions.** Our results indicated that overexpression of STOML1 and STOML2 was significantly associated with T1 and T2 stages of OSCC. STOML1 and STOML2 were mainly co-localized at the cell membrane and the cytoplasm. These findings suggested that either STOML1 or STOML2 may play critical roles in OSCC development and may serve as potential diagnostic biomarkers and therapeutic targets. (Oral Surg Oral Med Oral Pathol Oral Radiol 2020;129:591–599)

Oral squamous cell carcinoma (OSCC) is one of the most common malignancies worldwide. It is characterized by a high rate of incidence, recurrence, deterioration, and death.<sup>1–4</sup> Despite improvements in procedures associated with clinical diagnoses and treatment, the 5-year survival rate of patients with OSCC remains close to 50%.<sup>5</sup> In patients with OSCC, the rate of recurrence is much higher at the late tumor–node–metastasis (TNM) stages but remains lower at the early TNM stages.<sup>6,7</sup> However, specialized, sensitive biomarkers and effective therapeutics that may be utilized for early diagnosis and treatment of OSCC seem to be lacking. Thus, it is important to identify novel biomarkers that may act as useful tools that can assist in the diagnosis and treatment of OSCC.

Stomatin-like protein-1 (STOML1) and stomatin-like protein-2 (STOML2) belong to the stomatin superfamily.<sup>8</sup> There are 5 members in this family, namely, stomatin, STOML1, STOML2, stomatin-like protein-3 (STOML3), and podocin, which all exhibit a highly conserved characteristic structure, the core stomatin

domain.<sup>9</sup> Members of the stomatin superfamily of proteins are commonly found in mammals, plants, and bacteria.<sup>10</sup> STOML1 is a cell membrane protein that modulates acid sensing in ion channels.<sup>8</sup> Significantly high levels of STOML1 expression have been detected in the frontal lobe, cerebral cortex, hippocampus, and other basal ganglia.<sup>11</sup> Bioinformatic analyses conducted previously by our team indicated that mutation of the *STOML1* gene may be significantly associated with OSCC development.<sup>12</sup> However, very few studies have investigated the mechanisms underlying the association between STOML1 expression and OSCC development. However, many studies have reported that STOML2 may be a key protein that facilitates the proliferation of different cancer cells, such as esophageal squamous cell carcinoma,<sup>13</sup> rectal carcinoma,<sup>14</sup> epithelial ovarian carcinoma,<sup>15</sup> endometrial adenocarcinoma,<sup>16</sup> and papillary thyroid carcinoma,<sup>17</sup> among others.<sup>18,19</sup> Moreover, immunohistochemistry (IHC) results have shown that STOML3 expression was increased in the mesenchymal tumor areas of

## Statement of Clinical Significance

The expression of the stomatin-like protein-1 (STOML1) and stomatin-like protein-2 (STOML2) in oral squamous cell carcinoma (OSCC) pathology is little known. Here, we provide data about the expression of the STOML1 and STOML2 proteins in OSCC tissues in situ, and the results of our evaluation of their relationship to co-localization and their possible roles in OSCC.

gliosarcomas,<sup>20</sup> indicating that STOML3 may be associated with the mesenchymal component of gliosarcoma. Thus, these studies have indicated key roles for stomatin family members in carcinogenesis. The present study investigated the correlation between the expression levels of STOML1 and STOML2 and the pathologic stages of OSCC in situ by using multiple IHC staining of tissue microarrays. Furthermore, the co-localization effects of STOML1 and STOML2 on OSCC tissues and cell lines were evaluated.

## MATERIALS AND METHODS

### Tissue samples

Two commercial paraffin-embedded tissue microarrays were obtained from human oral cavity tissues (Biomax, Houston, TX): One array (OR208; n = 69) included 60 OSCC tissues and 9 normal oral tissues, where each tissue case was sectioned in triplicate; the other array (OR601 b; n = 60) included 50 OSCC tissues and 10 normal oral tissues, where each case was sectioned once. Individual clinical parameters, such as gender, TNM classification, clinical stage, and pathologic grade, per tissue section, are listed in Table I. Thus, 110 OSCC and 19 normal oral tissue sections were examined. One OSCC tissue section (ID: 601 b A3) split off during STOML2 antibody staining with the use of the multiple stain–destain–restain procedure (described below). All of the 110 OSCC tissues were examined for STOML1 expression, and 109 were examined for STOML2 expression.

### Immunofluorescent staining

Tca8113 cells were grown on coverslips and fixed with 2% paraformaldehyde in phosphate-buffered saline (PBS) for 15 minutes at 37°C. After blocking nonspecific signals by using 3% bovine serum albumin (BSA) in PBS for 30 minutes at room temperature, cells were incubated with primary anti-STOML1 (1:200) and anti-STOML2 (1:1000) antibodies for 1 hour and with corresponding secondary antibodies for 1 hour at room temperature, followed by immunofluorescent staining. Cells were observed under an Olympus FV1000 microscope with a × 60 oil-immersion lens, and positive fluorescent puncta of STOML1 and STOML2 were recorded.

### Multiple IHC staining

Multiplex IHC staining,<sup>21</sup> via a stain–destain–restain procedure, was used to detect several antigens. Tissue microarrays were deparaffinized with xylene and rehydrated with an alcohol series in a decreasing gradient. Tissue sections containing antigens were retrieved in 10 mM citrate buffer (pH 6.0) for 30 minutes, following incubation with 3% hydrogen peroxide for 30 minutes. After these tissue sections were washed with PBS, they were incubated with appropriate concentrations of primary anti-STOML1 antibodies (rabbit,

1:100) or anti-STOML2 antibodies (mouse, 1:200; Proteintech, Rosemont, IL) at 4°C, overnight. Next, the tissue sections were incubated with secondary antibodies (goat antirabbit immunoglobulin G [IgG]–horseradish peroxidase [HRP]; Beyotime, China) for 60 minutes at room temperature and stained by using a 3-amino-9-ethylcarbazole kit (AEC kit; GBI Labs, Bothell, WA) to detect positive signals. Hematoxylin was used for nuclear counterstaining. PBS was used as the negative control in place of primary antibodies. Anti-Ki67 antibodies (rabbit, 1:2000; Proteintech, Rosemont, IL), were used as a positive control, in place of primary antibodies, to check the staining process. Special anti-STOML1 or anti-STOML2 antibody-positive tissue sections were selected (e.g., colorectal cancer tissue sections), and immunostaining positive controls were set up against specific antigens.

### Cell culture

OSCC cell lines, including Tca-8113, HOEC, DOK, and NOMC, were seeded at a density of  $5 \times 10^4/\text{cm}^2$  in

collagen-coated 6-well plates with RPMI-1640 medium or DMEM/Ham's F12 medium supplemented by 10% fetal bovine serum and incubated at 37°C under a humidified atmosphere of 5% carbon dioxide.

### Western blot

Total proteins were collected from incubating cells with RIPA lysis buffer (Beyotime, China) containing a protease cocktail (Roche, Germany) for 30 minutes at 4°C. Following centrifugation at  $\times 14,000g$  at 4°C for 10 minutes, each lysate was transferred to a fresh 1.5-mL centrifuge tube on ice, and the protein concentration was determined by using a BCA assay (Thermo Fisher Scientific, Waltham, MA). For Western blot analysis, an equal amount of total protein was loaded on sodium dodecyl sulfate (SDS) polyacrylamide gel for electrophoresis purposes and transferred to a nitrocellulose membrane (Whatman, Germany). The nitrocellulose membrane was then blocked by using tris-buffered saline with Tween 20 (TBST) with 5% BSA for 30 minutes at room temperature. Candidate proteins were identified by using specific antibodies, followed by HRP-conjugated secondary antibodies. Bands were visualized by using an enhanced chemiluminescent substrate kit (ECL; Pierce Biotechnology, Waltham, MA) and a Tanon analysis system (Tanon, China).

### Immunostaining quantification

Images were recorded by using a scanner with a microscope (Aperio CS2/EM AC20; Leica, Wetzlar, Germany). Five fields from each section were randomly chosen under  $\times 20$  magnification. Special immune responses were analyzed by 3 independent examiners, who used intensity scores based on the German immunoreactive scoring (IRS) system.<sup>22,23</sup> The degree of positive signal intensity was determined by using the following scale: 0 = none; 1 = weak; 2 = moderate; 3 = intense; and 4 = strongly intense. The percentage of cells that showed positive signaling was recorded as follows: 0 = 0%; 1 = 1-25%; 2 = 26%–50%; 3 = 51%–75%; and 4 = 76%–100%. The final staining score was obtained by multiplying the 2 scores stated above. A score of 2 or less was considered “negative”, a score greater than 2 was considered “positive”, and these categories were used in the subsequent statistical analyses. Sections categorized as “positive” with a score of 3 or less was considered “low”, a score greater than 3 was considered “high”, and these score categories were used for statistical analyses.

### Statistical analysis

Positive signals and percentages were measured by using ImageJ (National Institutes of Health, Bethesda, MD). Statistical analyses of the  $\chi^2$  test, Fisher's exact test, 1-way analysis of variance (ANOVA), and

Student *t* test were performed with Graphpad prism 6 (Graphpad Software, Inc., San Jose, CA) and Excel (Microsoft Corp., Redmond, WA). All tests were 2-tailed, and statistical significance was set at  $P < .05$ .

## RESULTS

Images of multiplex IHC staining showed the overexpression of STOML1 and STOML2 in OSCC tissues. To investigate STOML1 and STOML2 expressions in OSCC tissue sections, multiplex IHC staining was performed on 109 OSCC specimens and on 19 specimens of normal oral/paracancerous tissues in situ. Positive signals were detected in 84 STOML1 specimens and 93 STOML2 specimens. Up to 77.1% and 85.3% (84 positive STOML1 antigen and 93 positive STOML2 antigen) of the 109 OSCC cases exhibited strong positive signals representing STOML1 and STOML2 expressions, compared with only 15.8% and 10.5% (3 positive STOML1 antigen and 2 positive STOML2 antigen) of the 19 normal oral tissue cases (score  $\geq 2$ ). Positive signals of STOML1 were detected in the membrane, cytoplasm, and nuclei of squamous epithelial cells in OSCC (Figure 1A), whereas positive signals of STOML2 were detected only in the cell membrane and the cytoplasm of cancerous squamous epithelia (Figure 1B). Image data indicated that both STOML1 and STOML2 were significantly overexpressed in OSCC lesions compared with those in normal tissues (see Figures 1A and 1B; Table II) ( $P < .001$ ). These results indicated that STOML1 and STOML2 showed potential as biomarkers for assisting in the diagnosis of OSCC.

### Positive correlation of STOML1 and STOML2 with T stages in the TNM classification

To investigate the effect of the coexisting overexpression of STOML1 and STOML2 in OSCC, expression levels of STOML1 and STOML2 in OSCC tissues were analyzed in relation to clinical stage, pathologic differentiation, and TNM stage. The association between STOML1 and STOML2 expressions and clinicopathologic factors are described in Table III. Images with high and low scores were divided into 2 OSCC groups, a score of 3 or less was considered “low” and a score greater than 3 was considered “high”. High-score and low-score groups were then analyzed in relation to clinicopathologic factors to determine if abnormal overexpression levels and co-localization of STOML1 and STOML2 were significantly correlated with OSCC development. Overexpression levels of both STOML1 and STOML2 were higher in early or advanced T stages in the TNM classification compared with those in normal tissues ( $P < .0001$ ) (Figure 2).  $\chi^2$  and Fisher's exact tests yielded similar results ( $P < .0001$ ) when the respective STOML1 and STOML2

expression levels of stages T1 and T2 as well as T3 and T4 were compared (see Table III). The percentages of STOML1<sup>High</sup> and STOML2<sup>High</sup> were up to 47.3% and 52.9% at the early stages (T1, T2) and up to 40% and 45% at advanced stages (T3, T4) in OSCC cases. Although a significant difference was observed for another clinical factor, gender ( $P < .005$ ), it was not considered for further investigation because the gender factor in this study was not normally distributed in a big population. As we collected samples and obtained information from tissue microarrays, female patients with OSCC were much fewer than male patients in this small group.

**Co-localization of STOML1 and STOML2 in OSCC tissues and cells**

Multiplex IHC positive signals were observed and recorded, and these results were analyzed via ImageJ software to show the intensity and distribution of STOML1 and STOML2 in cancer tissues and cells. The images showed that both STOML1 and STOML2 were located at the cell membranes and cytoplasm of OSCC, with similar staining distribution and intensity patterns (Figures 3A and 3B). The differences between staining distribution and intensity in cell nuclei were not measured because STOML2 was not located in the nucleus. Furthermore, to select appropriate cell lines for further testing in vitro, STOML1 and STOML2 expression levels in OSCC cell lines, including Tca-8113, HOEC, DOK, and Tca-8113, were detected by using Western blot. The results indicated that expression levels of both STOML1 and STOML2 in Tca-

8113 cells were higher than those in other tested cell lines, and the detected levels of these proteins were significantly higher in all OSCC cell lines than in the normal oral epithelial cell line (HOEC) (Figure 3C). Immunofluorescent staining was used to confirm the co-localization of STOML1 and STOML2 in Tca-8113 cells in vitro. Both STOML1 and STOML2 protein signals via immunofluorescent staining in the cell membrane and the cytoplasm overlapped, but only the STOML1 signals were observed in the cell nucleus (Figure 3D).

**DISCUSSION**

Approximately 500,000 patients with OSCC are newly diagnosed each year, and two-thirds of these patients are from South East Asian Countries.<sup>1,24</sup> Therefore, identification of novel biomarkers that show potential as diagnostic and therapeutic targets of OSCC should be considered important for improving the cure and survival rates of patients.<sup>25</sup> Furthermore, a comprehensive understanding of molecular mechanisms underlying OSCC development may contribute toward the early diagnosis of OSCC as well as the initiation of appropriate therapy.

A few studies have been conducted on STOML1, a member of the mammalian stomatin superfamily. Reportedly, high levels of STOML1 expression in the human brain are associated with Alzheimer disease.<sup>11,26</sup> STOML1, which is commonly located at the plasma membrane, interacts with stomatin, thereby affecting late endosome localization.<sup>27</sup> However, the association between STOML1

overexpression and the pathogenesis and pathophysiology of OSCC, as well as that of other human tumors, remains unclear.

STOML2, a mitochondrial protein located at the mitochondrial membrane,<sup>28</sup> is reportedly overexpressed in different cancers. Qu et al. evaluated the potential of STOML2 as a novel prognostic biomarker and suggested that STOML2 may promote head and neck squamous cell carcinoma by activating the interleukin (IL6)/STAT3 pathway.<sup>29</sup> In gallbladder cancer, high levels of STOML2 expression were associated with reduced 5-year survival rates.<sup>30</sup> Furthermore,

STOML2 expression may regulate survivin expression via the  $\beta$ -catenin pathway in non-small cell lung cancer.<sup>31,32</sup> STOML2 suppression may decrease the growth of human cervical cancer cells, and increase cisplatin-induced apoptosis by activating MEK/ERK signaling and suppressing the mitochondrial pathway.<sup>33</sup> In addition, STOML2 may play a role in hepatocellular carcinoma by regulating cell proliferation, migration, and epithelial-mesenchymal transition.<sup>34</sup>

The results of the present study indicated that STOML1 and STOML2 were remarkably increased in OSCC tissues and cells. Importantly,

immunofluorescent staining demonstrated that expression levels of both STOML1 and STOML2 were higher at OSCC stages T1-T1 or T3-T4 compared with oral/paracancerous stages. Furthermore, STOML1 and STOML2 expressions were localized in the cellular membranes and the cytoplasm, with more co-localization in OSCC cells in vivo and in vitro compared with normal oral/paracancerous tissues. These findings suggest that detection of STOML1 and STOML2 expression, either separately or in combination, may have prognostic implications. They may also have potential as novel diagnostic markers and therapeutic targets.

Interestingly, the co-localization of STOML1 and STOML2 was not completely coincidental. STOML1 and STOML2 were mostly localized in the cell membrane and the cytoplasm. However, STOML1 was also localized in the cell nucleus, which had no distribution of STOML2. These findings suggested that STOML1 and STOML2 may work together to modulate the OSCC process and that STOML1 may also have different role(s) in the regulation of OSCC by some transcriptional function because of its localization in the cell nucleus. Further studies will be required for an in-depth understanding of the regulative role played by STOML1 and STOML2 in OSCC and other cancers, in addition to the effect of co-localization of STOML1 and STOML2 on OSCC cells.

## CONCLUSIONS

Both STOML1 and STOML2 exhibited overexpression in OSCC tissues and in cell lines, suggesting that they may potentially serve as markers for assisting early diagnosis and evaluating medical treatments of this disease. Furthermore, while STOML1 and STOML2 were co-expressed in OSCC cell membrane and cytoplasm, only STOML1 was found within the nucleus. This suggests that the colocalization of STOML1 and STOML2 may play a role in OSCC development.

## FUNDINGS

Financial support was provided by the Science and Technology Program, the Science and Technology Innovation Committee of Shenzhen (Grant No. JCYJ20160520174247964); Opening Project of Key Laboratory of Shaanxi Province for Craniofacial Precision Medicine Research, College of Stomatology, Xi'an Jiaotong University (Grant No. 2016 LHM-KFKT010); and 2018 LHM-KFKT007. In addition, this study was also supported by the Instrumental Analysis Center of Shenzhen University (Lihu Campus) for applying research instruments.

“-” means no applicable or negative in IHC markers.

TNM grading:

T - Primary tumor

Tx - Primary tumor cannot be assessed

T0 - No evidence of primary tumor

Tis - Carcinoma in situ; intraepithelial or invasion of lamina propria

T1 - Tumor invades submucosa

T2 - Tumor invades muscularis propria

T3 - Tumor invades through muscularis propria into subserosa or into non-peritonealized pericolic or perirectal tissues.

T4 - Tumor directly invades other organs or structures and/or perforate visceral peritoneum

N - Regional lymph nodes

Nx - Regional lymph nodes cannot be assessed

N0 - No regional lymph node metastasis

N1 - Metastasis in 1 to 3 regional lymph nodes

N2 - Metastasis in 4 or more regional lymph nodes

M - Distant metastasis

Mx - Distant metastasis cannot be assessed

M0 - No distant metastasis

M1 - Distant metastasis
